Dennis Sgroi

Mark G. Erlander

FIELD OF THE INVENTION

The invention relates to the identification and use of gene expression profiles, or patterns, involved in breast cancer progression. The gene expression profiles, whether embodied in nucleic acid expression, protein expression, or other expression formats, are used in the study and/or diagnosis of cells and tissue during breast cancer progression as well as for the study and/or determination of prognosis of a patient. When used for diagnosis or prognosis, the profiles are used to predict the status and/or phenotype of cells and tissues relative to breast cancer and the treatment thereof.

BACKGROUND OF THE INVENTION

Breast cancer is by far the most common cancer among women. Each year, more than 180,000 and 1 million women in the U.S. and worldwide, respectively, are diagnosed with breast cancer. Breast cancer is the leading cause of death for women between ages 50-55, and is the most common non-preventable malignancy in women in the Western Hemisphere. An estimated 2,167,000 women in the United States are currently living with the disease (National Cancer Institute, Surveillance Epidemiology and End Results (NCI SEER) program, *Cancer Statistics* sd-71385

- 2 -

Review (CSR), www-seer.ims.nci.nih.gov/Publications/CSR1973 (1998)). Based on cancer rates from 1995 through 1997, a report from the National Cancer Institute (NCI) estimates that about 1 in 8 women in the United States (approximately 12.8 percent) will develop breast cancer during her lifetime (NCI's Surveillance, Epidemiology, and End Results Program (SEER) publication *SEER Cancer Statistics Review 1973-1997*). Breast cancer is the second most common form of cancer, after skin cancer, among women in the United States. An estimated 250,100 new cases of breast cancer are expected to be diagnosed in the United States in 2001. Of these, 192,200 new cases of more advanced (invasive) breast cancer are expected to occur among women (an increase of 5% over last year), 46,400 new cases of early stage (*in situ*) breast cancer are expected to occur among women (up 9% from last year), and about 1,500 new cases of breast cancer are expected to be diagnosed in men (Cancer Facts & Figures 2001 American Cancer Society). An estimated 40,600 deaths (40,300 women, 400 men) from breast cancer are expected in 2001. Breast cancer ranks second only to lung cancer among causes of cancer deaths in women. Nearly 86% of women who are diagnosed with breast cancer are likely to still be alive five years later, though 24% of them will die of breast cancer after 10 years, and nearly half (47%) will die of breast cancer after 20 years.

Every woman is at risk for breast cancer. Over 70 percent of breast cancers occur in women who have no identifiable risk factors other than age (U.S. General Accounting Office. Breast Cancer, 1971-1991: Prevention, Treatment and Research. GAO/PEMD-92-12; 1991). Only 5 to 10% of breast cancers are linked to a family history of breast cancer (Henderson IC, Breast Cancer. In: Murphy GP, Lawrence WL, Lenhard RE (eds). *Clinical Oncology*. Atlanta, GA: American Cancer Society; 1995:198-219).

Each breast has 15 to 20 sections called lobes. Within each lobe are many smaller lobules. Lobules end in dozens of tiny bulbs that can produce milk. The lobes, lobules, and bulbs are all linked by thin tubes called ducts. These ducts lead to the nipple in the center of a dark area of skin called the areola. Fat surrounds the lobules and ducts. There are no muscles in the breast, but muscles lie under each breast and cover the ribs. Each breast also contains blood

- 3 -

vessels and lymph vessels. The lymph vessels carry colorless fluid called lymph, and lead to the lymph nodes. Clusters of lymph nodes are found near the breast in the axilla (under the arm), above the collarbone, and in the chest.

Breast tumors can be either benign or malignant. Benign tumors are not cancerous, they do not spread to other parts of the body, and are not a threat to life. They can usually be removed, and in most cases, do not come back. Malignant tumors are cancerous, and can invade and damage nearby tissues and organs. Malignant tumor cells may metastasize, entering the bloodstream or lymphatic system. When breast cancer cells metastasize outside the breast, they are often found in the lymph nodes under the arm (axillary lymph nodes). If the cancer has reached these nodes, it means that cancer cells may have spread to other lymph nodes or other organs, such as bones, liver, or lungs.

Major and intensive research has been focussed on early detection, treatment and prevention. This has included an emphasis on determining the presence of precancerous or cancerous ductal epithelial cells. These cells are analyzed, for example, for cell morphology, for protein markers, for nucleic acid markers, for chromosomal abnormalities, for biochemical markers, and for other characteristic changes that would signal the presence of cancerous or precancerous cells. This has led to various molecular alterations that have been reported in breast cancer, few of which have been well characterized in human clinical breast specimens. Molecular alterations include presence/absence of estrogen and progesterone steroid receptors, HER-2 expression/amplification (Mark HF, et al. HER-2/neu gene amplification in stages I-IV breast cancer detected by fluorescent in situ hybridization. Genet Med; 1(3):98-103 1999), Ki-67 (an antigen that is present in all stages of the cell cycle except G0 and used as a marker for tumor cell proliferation, and prognostic markers (including oncogenes, tumor suppressor genes, and angiogenesis markers) like p53, p27, Cathepsin D, pS2, multi-drug resistance (MDR) gene, and CD31.

Examination of cells by a trained pathologist has also been used to establish whether ductal epithelial cells are normal (i.e. not precancerous or cancerous or having another

- 4 -

noncancerous abnormality), precancerous (i.e. comprising hyperplasia, atypical ductal hyperplasia (ADH)) or cancerous (comprising ductal carcinoma *in situ*, or DCIS, which includes low grade ductal carcinoma *in situ*, or LG-DCIS, and high grade ductal carcinoma in situ, or HG-DCIS) or invasive (ductal) carcinoma (IDC). Pathologists may also identify the occurrence of lobular carcinoma in situ (LCIS) or invasive lobular carcinoma (ILC). Breast cancer progression may be viewed as the occurrence of abnormal cells, such as those of ADH, DCIS, IDC, LCIS, and/or ILC, among normal cells.

It remains unclear whether normal cells become hyperplastic (such as ADH) and then progressing on to become malignant (DCIS, IDC, LCIS, and/or ILC) or whether normal cells are able to directly become malignant without transitioning through a hyperplastic stage. It has been observed, however, that the presence of ADH indicates a higher likelihood of developing a malignancy. This has resulting in treatment of patients with ADH to begin treatment with an antineoplastic/antitumor agent such as tamoxifen. This is in contrast to the treatment of patients with malignant breast cancer which usually includes surgical removal.

The rational development of preventive, diagnostic and therapeutic strategies for women at risk for breast cancer would be aided by a molecular map of the tumorigenesis process. Relatively little is known of the molecular events that mediate the transition of normal breast cells to the various stages of breast cancer progression. In particular, there is a significant paucity of information regarding the genetic changes that are associated with the earliest stages of human breast cancer, which include the transition of normal breast cells to atypical hyperplastic and/or pre-invasive malignant cells (carcinoma *in situ*).

Molecular means of identifying the differences between normal, non-cancerous cells and cancerous cells (in general) have also been the focus of intense study. The use of cDNA libraries to analyze differences in gene expression patterns in normal versus tumorigenic cells has been described (USP 4,981,783). DeRisi et al. (1996) describe the analysis of gene expression patterns between two cell lines: UACC-903, which is a tumorigenic human melanoma cell line, and UACC-903(+6), which is a chromosome 6 suppressed non-tumorigenic form of UACC-903.

- 5 -

Labeled cDNA probes made from mRNA from these cell lines were applied to DNA microarrays containing 870 different cDNAs and controls. Genes that were preferentially expressed in one of the two cell lines were identified.

Golub et al. (1999) describe the use of gene expression monitoring as means to cancer class discovery and class prediction between acute myeloid leukemia (AML) and acute lymphoblastic leukemia (ALL). Their approach to class predictors used a neighborhood analysis followed by cross-validation of the validity of the predictors by withholding one sample and building a predictor based only on the remaining samples. This predictor is then used to predict the class of the withheld sample. They also used cluster analysis to identify new classes (or subtypes) within the AML and ALL.

Gene expression patterns in human breast cancers have been described by Perou et al. (1999), who studied gene expression between cultured human mammary epithelia cells (HMEC) and breast tissue samples by use of microarrays comprising about 5000 genes. They used a clustering algorithm to identify patterns of expression in HMEC and tissue samples. Perou et al. (2000) describe the use of clustered gene expression profiles to classify subtypes of human breast tumors. Hedenfalk et al. describe gene expression profiles in BRCA1 mutation positive, BRCA2 mutation positive, and sporadic tumors. Sgroi et al. also analyzed gene expression of normal and breast cancer cells from a single patient. Using gene expression patterns to distinguish breast tumor subclasses and predict clinical implications is described by Sorlie et al. and West et al.

All of the above described approaches, however, utilize heterogeneous populations of cells found in culture or in a biopsy to obtain information on gene expression patterns. The use of such populations may result in the inclusion or exclusion of multiple genes from the patterns. For this and the lack of statistical robustness reasons, the gene expression patterns observed by the above described approaches provide little confidence that the differences in gene expression may be meaningfully associated with the stages of breast cancer.

SUMMARY OF THE INVENTION

The present invention relates to the identification and use of gene expression patterns (or profiles or “signatures”) which are correlated with (and thus able to discriminate between) cells in various stages of breast cancer. Broadly defined, these stages are non-malignant versus malignant, but may also be viewed as normal versus atypical (optionally including reactive and pre-neoplastic) versus cancerous. Another definition of the stages is normal versus precancerous (e.g. atypical ductal hyperplasia (ADH) or atypical lobular hyperplasia (ALH)) versus cancerous (e.g. carcinoma *in situ* such as DCIS and/or LCIS) versus invasive (e.g. carcinomas such as IDC and/or ILC). DCIS may be further viewed as low grade versus high grade or grade I through grade III.

The gene expression patterns comprise one or more than one gene capable of discriminating between various stages of breast cancer with significant accuracy. The gene(s) are identified as correlated with various stages of breast cancer such that the levels of their expression are relevant to a determination of the stage of breast cancer of a cell. Thus in one aspect, the invention provides a method to determine the stage of breast cancer of a subject afflicted with, or suspected of having, breast cancer by assaying a cell containing sample from said subject for expression of one or more than one gene disclosed herein as correlated with one or more stages of breast cancer.

Gene expression patterns of the invention are identified by analysis of gene expression in multiple samples of each stage to be studied. The overall gene expression profile of each sample is obtained by analyzing the expressed or unexpressed state of genes in each stage relative to each other (one gene to another across all genes). This overall profile is then analyzed to identify genes that are positively, or negatively, correlated, with a stage of breast cancer relative to other genes. An expression profile of a subset of human genes may then be identified by the methods of the present invention as correlated with breast cancer. The use of multiple samples increases the confidence which which a gene may be believed to be correlated with a particular stage.

- 7 -

Without sufficient confidence, it remains unpredictable whether a particular gene is actually correlated with a stage of breast cancer and also unpredictable whether a particular gene may be successfully used to identify the stage of an unknown breast cancer cell sample.

A profile of genes that are highly correlated with one stage relative to another may be used to assay an sample from a subject afflicted with, or suspected of having, breast cancer to identify the stage of breast cancer to which the sample belongs. Such an assay may be used as part of a method to determine the therapeutic treatment for said subject based upon the stage(s) of breast cancer identified.

The correlated genes may be used singly with significant accuracy or in combination to increase the ability to accurately discriminate between various stages of breast cancer. The present invention thus provides means for correlating a molecular expression phenotype with a physiological (cellular) stage or state. This correlation provides a way to molecularly diagnose and/or monitor a cell's status in comparison to different cancerous versus non-cancerous phenotypes as disclosed herein. Additional uses of the correlated gene(s) are in the classification of cells and tissues; determination of diagnosis and/or prognosis; and determination and/or alteration of therapy.

The ability to discriminate is conferred by the identification of expression of the individual genes as relevant and not by the form of the assay used to determine the actual level of expression. An assay may utilize any identifying feature of an identified individual gene as disclosed herein as long as the assay reflects, quantitatively or qualitatively, expression of the gene. Identifying features include, but are not limited to, unique nucleic acid sequences used to encode (DNA), or express (RNA), said gene or epitopes specific to, or activities of, a protein encoded by said gene. All that is required is the identity of the gene(s) necessary to discriminate between stages of breast cancer and an appropriate cell containing sample for use in an expression assay.

In one aspect, the invention provides for the identification of the gene expression patterns by analyzing global, or near global, gene expression from single cells or homogenous cell

populations which have been dissected away from, or otherwise isolated or purified from, contaminating cells beyond that possible by a simple biopsy. Because the expression of numerous genes fluctuate between cells from different patients as well as between cells from the same patient sample, multiple individual gene expression patterns are used as reference data to generate models which in turn permit the identification of individual gene(s) that are most highly correlated with particular breast cancer stages and/or have the best the ability to discriminate cells of one stage from another.

In another aspect, the invention provides physical and methodological means for detecting the expression of gene(s) identified by the models generated by individual expression patterns. These means may be directed to assaying one or more aspect of the DNA template(s) underlying the expression of the gene(s), of the RNA used as an intermediate to express the gene(s), or of the proteinaceous product expressed by the gene(s).

In a further aspect, the gene(s) identified by a model as capable of discriminating between breast cancer stages may be used to identify the cellular state of an unknown sample of cell(s) from the breast. Preferably, the sample is isolated via non-invasive means. The expression of said gene(s) in said unknown sample may be determined and compared to the expression of said gene(s) in reference data of gene expression patterns from the various stages of breast cancer. Optionally, the comparison to reference samples may be by comparison to the model(s) constructed based on the reference samples.

One advantage provided by the present invention is that contaminating, non-breast cells (such as infiltrating lymphocytes or other immune system cells) are not present to possibly affect the genes identified or the subsequent analysis of gene expression to identify the status of suspected breast cancer cells. Such contamination is present where a biopsy is used to generate gene expression profiles.

While the present invention has been described mainly in the context of human breast cancer, it may be practiced in the context of breast cancer of any animal known to be potentially afflicted by breast cancer. Preferred animals for the application of the present invention are

- 9 -

mammals, particularly those important to agricultural applications (such as, but not limited to, cattle, sheep, horses, and other “farm animals”) and for human companionship (such as, but not limited to, dogs and cats).

BRIEF DESCRIPTION OF THE FIGURES

Figure 1 is a schematic representing a data matrix of a pair-wise comparison between Grade I and Grade III DCIS among 16 samples (across the top) and a large number of genes identified by “CloneID”) along the left hand side.

Figure 2 is a table showing the actual weight data corresponding to Example II, where the data from ten genes (by CloneID number vertically) are compared to DCIS and ADH samples (across the top). Some data in the table has been vertically presented to permit the table to be displayed on a single sheet. The use of “-“ with data in the table reflects genes that are more highly expressed in ADH relative to DCIS. The absence of “-“ reflects genes that are more highly expressed in DCIS relative to ADH.

Figure 3 is a table showing the actual weight data corresponding to Example VII, where the data from over 300 genes (by CloneID number vertically) are compared to DCIS and ADH samples (across the top). Some data in the table has been vertically presented solely for display purposes. The use of “-“ with data in the table reflects genes that are more highly expressed in ADH relative to DCIS. The absence of “-“ reflects genes that are more highly expressed in DCIS relative to ADH.

Figure 4 is a table showing the actual weight data corresponding to Example VIII, where the data from over 300 genes (by CloneID number vertically) are compared to samples (across the top) from two grades of DCIS. The use of “-“ with data in the table reflects genes that are more

- 10 -

highly expressed in grade I relative to grade III. The absence of “-“ reflects genes that are more highly expressed in grade III relative to grade I.

DETAILED DESCRIPTION OF THE SPECIFIC EMBODIMENTS

Definitions of terms as used herein:

A gene expression “pattern” or “profile” or “signature” refers to the relative expression of a gene between two or more stages of breast cancer which is correlated with being able to distinguish between said stages.

A “gene” is a polynucleotide that encodes a discrete product, whether RNA or proteinaceous in nature. It is appreciated that more than one polynucleotide may be capable of encoding a discrete product. The term includes alleles and polymorphisms of a gene that encodes the same product, or a functionally associated (including gain, loss, or modulation of function) analog thereof, based upon chromosomal location and ability to recombine during normal mitosis.

A “stage” or “stages” (or equivalents thereof) of breast cancer refer to a physiologic state of a breast cell as defined by known cytological or histological (including immunohistology, histochemistry, and immunohistochemistry) procedures and are readily known to skilled in the art. Non-limiting examples include normal versus abnormal, non-cancerous versus cancerous, the different stages described herein (e.g. hyperplastic, carcinoma, and invasive), and grades within different stages (e.g. grades I, II, or III or the equivalents thereof within cancerous stages).

The terms “correlate” or “correlation” or equivalents thereof refer to an association between expression of one or more genes and a physiologic state of a breast cell to the exclusion of one or more other stages and/or identified by use of the methods as described herein. A gene may be expressed at higher or lower levels and still be correlated with one or more breast cancer stages.

- 11 -

A “polynucleotide” is a polymeric form of nucleotides of any length, either ribonucleotides or deoxyribonucleotides. This term refers only to the primary structure of the molecule. Thus, this term includes double- and single-stranded DNA and RNA. It also includes known types of modifications including labels known in the art, methylation, “caps”, substitution of one or more of the naturally occurring nucleotides with an analog, and internucleotide modifications such as uncharged linkages (e.g., phosphorothioates, phosphorodithioates, etc.), as well as unmodified forms of the polynucleotide.

The term “amplify” is used in the broad sense to mean creating an amplification product can be made enzymatically with DNA or RNA polymerases. “Amplification,” as used herein, generally refers to the process of producing multiple copies of a desired sequence, particularly those of a sample. “Multiple copies” mean at least 2 copies. A “copy” does not necessarily mean perfect sequence complementarity or identity to the template sequence.

By corresponding is meant that a nucleic acid molecule shares a substantial amount of sequence identity with another nucleic acid molecule. Substantial amount means at least 95%, usually at least 98% and more usually at least 99%, and sequence identity is determined using the BLAST algorithm, as described in Altschul et al. (1990), J. Mol. Biol. 215:403-410 (using the published default setting, i.e. parameters w=4, t=17). Methods for amplifying mRNA are generally known in the art, and include reverse transcription PCR (RT-PCR) and those described in U.S. Patent Application (number to be assigned) entitled “Nucleic Acid Amplification” filed on October 25, 2001 as attorney docket number 485772002900 as well as U.S. Provisional Patent Applications 60/298,847 (filed June 15, 2001) and 60/257,801 (filed December 22, 2000), all of which are hereby incorporated by reference in their entireties as if fully set forth. Alternatively, RNA may be directly labeled as the corresponding cDNA by methods known in the art.

A “microarray” is a linear or two-dimensional array of preferably discrete regions, each having a defined area, formed on the surface of a solid support such as, but not limited to, glass, plastic, or synthetic membrane. The density of the discrete regions on a microarray is

- 12 -

determined by the total numbers of immobilized polynucleotides to be detected on the surface of a single solid phase support, preferably at least about $50/\text{cm}^2$, more preferably at least about $100/\text{cm}^2$, even more preferably at least about $500/\text{cm}^2$, but preferably below about $1,000/\text{cm}^2$. Preferably, the arrays contain less than about 500, about 1000, about 1500, about 2000, about 2500, or about 3000 immobilized polynucleotides in total. As used herein, a DNA microarray is an array of oligonucleotides or polynucleotides placed on a chip or other surfaces used to hybridize to amplified or cloned polynucleotides from a sample. Since the position of each particular group of primers in the array is known, the identities of a sample polynucleotides can be determined based on their binding to a particular position in the microarray.

Because the invention relies upon the identification of genes that are over- or under-expressed, one embodiment of the invention involves determining expression by hybridization of mRNA, or an amplified or cloned version thereof, of a sample cell to a polynucleotide that is unique to a particular gene sequence. Preferred polynucleotides of this type contain at least about 20, at least about 22, at least about 24, at least about 26, at least about 28, at least about 30, or at least about 32 consecutive basepairs of a gene sequence that is not found in other gene sequences. The term "about" as used in the previous sentence refers to an increase or decrease of 1 from the stated numerical value. Even more preferred are polynucleotides of at least about 50, at least about 100, and at least about 150 basepairs of a gene sequence that is not found in other gene sequences. The term "about" as used in the preceding sentence refers to an increase or decrease of 10% from the stated numerical value.

Alternatively, and in another embodiment of the invention, gene expression may be determined by analysis of expressed protein in a cell sample of interest by use of one or more antibodies specific for one or more epitopes of individual gene products (proteins) in said cell sample. Such antibodies are preferably labeled to permit their easy detection after binding to the gene product.

The term "label" refers to a composition capable of producing a detectable signal indicative of the presence of the labeled molecule. Suitable labels include radioisotopes,

- 13 -

nucleotide chromophores, enzymes, substrates, fluorescent molecules, chemiluminescent moieties, magnetic particles, bioluminescent moieties, and the like. As such, a label is any composition detectable by spectroscopic, photochemical, biochemical, immunochemical, electrical, optical or chemical means.

The term “support” refers to conventional supports such as beads, particles, dipsticks, fibers, filters, membranes and silane or silicate supports such as glass slides.

As used herein, a “breast tissue sample” or “breast cell sample” refers to a sample of breast tissue or fluid isolated from an individual suspected of being afflicted with, or at risk of developing, breast cancer. Such samples are primary isolates (in contrast to cultured cells) and may be collected by any non-invasive means, including, but not limited to, ductal lavage, fine needle aspiration, needle biopsy, the devices and methods described in U.S. Patent 6,328,709, or any other suitable means recognized in the art. Alternatively, the “sample” may be collected by an invasive method, including, but not limited to, surgical biopsy.

“Expression” and “gene expression” include transcription and/or translation of nucleic acid material.

As used herein, the term “comprising” and its cognates are used in their inclusive sense; that is, equivalent to the term “including” and its corresponding cognates.

Conditions that “allow” an event to occur or conditions that are “suitable” for an event to occur, such as hybridization, strand extension, and the like, or “suitable” conditions are conditions that do not prevent such events from occurring. Thus, these conditions permit, enhance, facilitate, and/or are conducive to the event. Such conditions, known in the art and described herein, depend upon, for example, the nature of the nucleotide sequence, temperature, and buffer conditions. These conditions also depend on what event is desired, such as hybridization, cleavage, strand extension or transcription.

Sequence “mutation,” as used herein, refers to any sequence alteration in the sequence of a gene disclosed herein interest in comparison to a reference sequence. A sequence mutation includes single nucleotide changes, or alterations of more than one nucleotide in a sequence, due

- 14 -

to mechanisms such as substitution, deletion or insertion. Single nucleotide polymorphism (SNP) is also a sequence mutation as used herein. Because the present invention is based on the relative level of gene expression, mutations in non-coding regions of genes as disclosed herein may also be assayed in the practice of the invention.

“Detection” includes any means of detecting, including direct and indirect detection of gene expression and changes therein. For example, “detectably less” products may be observed directly or indirectly, and the term indicates any reduction (including the absence of detectable signal). Similarly, “detectably more” product means any increase, whether observed directly or indirectly.

Unless defined otherwise all technical and scientific terms used herein have the same meaning as commonly understood to one of ordinary skill in the art to which this invention belongs.

Specific Embodiments

The present invention relates to the identification and use of gene expression patterns (or profiles or “signatures”) which discriminate between (or are correlated with) cells in various stages of breast cancer. Such patterns may be determined by the methods of the invention by use of a number of reference cell or tissue samples, such as those reviewed by a pathologist of ordinary skill in the pathology of breast cancer, which reflect various stages of breast cancer. Because the overall gene expression profile differs from person to person, cancer to cancer, and cancer cell to cancer cell, correlations between certain cell states and genes expressed or underexpressed may be made as disclosed herein to identify genes that are capable of discriminating between different breast cancer states.

The present invention may be practiced with any number of genes believed, or likely to be, differentially expressed in breast cancer cells. In Example I below, approximately 12,000 genes were used to identify hundreds of genes capable of discriminating between various stages of breast cancer as shown in Examples 2-9. The identification may be made by using expression

- 15 -

profiles of various homogenous normal and breast cancer cell populations, which were isolated by microdissection, such as, but not limited to, laser capture microdissection (LCM) of 100-1000 cells. Each gene of the expression profile may be assigned weights based on its ability to discriminate between two or more stages of breast cancer (see Example I). The magnitude of each assigned weight indicates the extent of difference in expression between the two groups and is an approximation of the ability of expression of the gene to discriminate between the two groups (and thus stages). The magnitude of each assigned weight also approximates the extent of correlation between expression of individual gene(s) and particular breast cancer stages.

It should be noted that merely high levels of expression in cells from a particular stage or stages does not necessarily mean that a gene will be identified as having a high absolute weight value.

Genes with top ranking weights (in absolute terms) may be used to generate models of gene expressions that would maximally discriminate between the two groups. Alternatively, genes with top ranking weights (in absolute terms) may be used in combination with genes with lower weights without significant loss of ability to discriminate between groups. Such models may be generated by any appropriate means recognized in the art, including, but not limited to, cluster analysis, supported vector machines, neural networks or other algorithm known in the art. The models are capable of predicting the classification of a unknown sample based upon the expression of the genes used for discrimination in the models. "Leave one out" cross-validation may be used to test the performance of various models and to help identify weights (genes) that are uninformative or detrimental to the predictive ability of the models. Cross-validation may also be used to identify genes that enhance the predictive ability of the models.

The gene(s) identified as correlated with particular breast cancer stages by the above models provide the ability to focus gene expression analysis to only those genes that contribute to the ability to identify a cell as being in a particular stage of breast cancer relative to another stage or stages. The expression of other genes in a breast cancer cell would be relatively unable to provide information concerning, and thus assist in the discrimination of, different stages of

- 16 -

breast cancer. For example, the alpha subunit of human topoisomerase II (identified by CloneID 825470) has been found to be useful in discriminations between normal and atypical cells (ADH and DCIS and IDC and LCIS), between normal and ADH cells compared to DCIS and IDC cells, between normal and DCIS cells, between ADH and DCIS cells, between grade I and grade III DCIS cells, and between grade I and grade III IDC cells but not between normal and ADH cells (see Examples II to IX below). Thus expression of this topoisomerase II subunit would be utilized in models to discriminate between the above listed stages but not for discerning normal from ADH cells. This type of analysis is readily incorporated into algorithms used to generate models with reference gene expression data.

As will be appreciated by those skilled in the art, the models are highly useful with even a small set of reference gene expression data and can become increasingly accurate with the inclusion of more reference data although the incremental increase in accuracy will likely diminish with each additional datum. The preparation of additional reference gene expression data using genes identified and disclosed herein for discriminating between different stages of breast cancer is routine and may be readily performed by the skilled artisan to permit the generation of models as described above to predict the status of an unknown sample based upon the expression levels of those genes.

To determine the expression levels of genes in the practice of the present invention, any method known in the art may be utilized. In one preferred embodiment of the invention, expression based on detection of RNA which hybridizes to the genes identified and disclosed herein is used. This is readily performed by any RNA detection or amplification+detection method known or recognized as equivalent in the art such as, but not limited to, reverse transcription-PCR, the methods disclosed in U.S. Patent Application (number to be assigned) entitled "Nucleic Acid Amplification" filed on October 25, 2001 as attorney docket number 485772002900 as well as U.S. Provisional Patent Applications 60/298,847 (filed June 15, 2001) and 60/257,801 (filed December 22, 2000), and methods to detect the presence, or absence, of RNA stabilizing or destabilizing sequences.

- 17 -

Alternatively, expression based on detection of DNA status may be used. Detection of the DNA of an identified gene as methylated or deleted may be used for genes that have decreased expression in correlation with a particular breast cancer stage. This may be readily performed by PCR based methods known in the art. Conversely, detection of the DNA of an identified gene as amplified may be used for genes that have increased expression in correlation with a particular breast cancer stage. This may be readily performed by PCR based, fluorescent in situ hybridization (FISH) and chromosome in situ hybridization (CISH) methods known in the art.

Expression based on detection of a presence, increase, or decrease in protein levels or activity may also be used. Detection may be performed by any immunohistochemistry (IHC) based, blood based (especially for secreted proteins), antibody (including autoantibodies against the protein) based, ex foliate cell (from the cancer) based, mass spectroscopy based, and image (including used of labeled ligand) based method known in the art and recognized as appropriate for the detection of the protein. Antibody and image based methods are additionally useful for the localization of tumors after determination of cancer by use of cells obtained by a non-invasive procedure (such as ductal lavage or fine needle aspiration), where the source of the cancerous cells is not known. A labeled antibody or ligand may be used to localize the carcinoma(s) within a patient.

A preferred embodiment using a nucleic acid based assay to determine expression is by immobilization of one or more of the genes identified herein on a solid support, including, but not limited to, a solid substrate as an array or to beads or bead based technology as known in the art. Alternatively, solution based expression assays known in the art may also be used. The immobilized gene(s) may be in the form of polynucleotides that are unique or otherwise specific to the gene(s) such that the polynucleotide would be capable of hybridizing to a DNA or RNA corresponding to the gene(s). These polynucleotides may be the full length of the gene(s) or be short sequences of the genes that are optionally minimally interrupted (such as by mismatches or

- 18 -

inserted non-complementary basespairs) such that hybridization with a DNA or RNA corresponding to the gene(s) is not affected.

The immobilized gene(s) may be used to determine the state of nucleic acid samples prepared from sample breast cell(s) for which the pre-cancer or cancer status is not known or for confirmation of a status that is already assigned to the sample breast cell(s). Without limiting the invention, such a cell may be from a patient suspected of being afflicted with, or at risk of developing, breast cancer. The immobilized polynucleotide(s) need only be sufficient to specifically hybridize to the corresponding nucleic acid molecules derived from the sample. While even a single correlated gene sequence may be able to provide adequate accuracy in discriminating between two breast cancer cell stages, two or more, three or more, four or more, five or more, six or more, seven or more, eight or more, nine or more, ten or more, or eleven or more of the genes identified herein may be used as a subset capable of discriminating may be used in combination to increase the accuracy of the method. The invention specifically contemplates the selection of more than one, two or more, three or more, four or more, five or more, six or more, seven or more, eight or more, nine or more, ten or more, or eleven or more of the genes disclosed in the tables and figures herein for use as a subset in the identification of whether an unknown or suspicious breast cancer sample is normal or is in one or more stages of breast cancer. Optionally, the genes used will not include CloneID 809507, which is also known as GenBank accession number AA454563, described as an EST with high similarity to CD63 but of unknown function.

In embodiments where only one or a few genes are to be analyzed, the nucleic acid derived from the sample breast cancer cell(s) may be preferentially amplified by use of appropriate primers such that only the genes to be analyzed are amplified to reduce contaminating background signals from other genes expressed in the breast cell. Alternatively, and where multiple genes are to be analyzed or where very few cells (or one cell) is used, the nucleic acid from the sample may be globally amplified before hybridization to the immobilized

- 19 -

polynucleotides. Of course RNA, or the cDNA counterpart thereof may be directly labeled and used, without amplification, by methods known in the art.

The above assay embodiments may be used in a number of different ways to identify or detect the breast cancer stage, if any, of a breast cancer cell sample from a patient. In many cases, this would reflect a secondary screen for the patient, who may have already undergone mammography or physical exam as a primary screen. If positive, the subsequent needle biopsy, ductal lavage, fine needle aspiration, or other analogous methods may provide the sample for use in the above assay embodiments. The present invention is particularly useful in combination with non-invasive protocols, such as ductal lavage or fine needle aspiration, to prepare a breast cell sample. The current analysis of ductal lavage samples is by cytological examination by a trained pathologist who classifies the samples in terms that are at least partly subjective: unsatisfactory (too few cells), benign (including fibrocystic change), atypical (or mild atypia), suspicious (or marked atypia), or malignant.

The present invention provides a more objective set of criteria, in the form of gene expression profiles of a discrete set of genes, to discriminate (or delineate) between meaningful stages (or classes) of breast cancer cells. In particularly preferred embodiments of the invention, the assays are used to discriminate between ADH and DCIS or otherwise malignant cells, which is a critical determination for decisions concerning subsequent treatment and therapy for the patient. Another particularly preferred determination is between the three grades (I, II, III) of carcinomas *in situ* as well as the discrimination between grade III carcinomas *in situ* and invasive carcinomas. Other pairwise comparisons that are provided by the invention include, but are not limited to, normal versus ADH, normal versus carcinoma *in situ*, normal versus invasive, normal versus cancerous (i.e. carcinoma present), ADH versus cancerous, and carcinoma *in situ* versus invasive. With the use of alternative algorithms, such as neural networks, comparisons that discriminate between multiple (more than pairwise) classes may also be performed. It is believed by the inventors that the present invention is the first example of objective, molecular criteria for making these discriminations.

- 20 -

In one embodiment of the invention, the isolation and analysis of a breast cancer cell sample may be performed as follows:

- (1) Ductal lavage or other non-invasive procedure is performed on a patient to obtain a sample.
- (2) Sample is prepared and coated onto a microscope slide. Note that ductal lavage results in clusters of cells that are cytologically examined as stated above.
- (3) Pathologist or image analysis software scans the sample for the presence of atypical cells.
- (4) If atypical cells are observed, those cells are harvested (e.g. by microdissection such as LCM).
- (5) RNA is extracted from the harvested cells.
- (6) RNA is purified, amplified, and labeled.
- (7) Labeled nucleic acid is contacted with a microarray containing polynucleotides of the genes identified herein as correlated to discriminations between two or more stages of breast cancer under hybridization conditions, then processed and scanned to obtain a pattern of intensities of each spot (relative to a control for general gene expression in cells) which determine the level of expression of the gene(s) in the cells.
- (8) The pattern of intensities is analyzed by comparison to the expression patterns of the genes in known samples of normal and breast cancer cells (relative to the same control).

A specific example of the above method would be performing ductal lavage following a primary screen, observing and collecting atypical cells for analysis. The comparison to known expression patterns, such as that made possible by a model generated by an algorithm (such as, but not limited to nearest neighbor type analysis, SVM, or neural networks) with reference gene expression data for the different breast cancer stages, identifies the cells as being most likely ADH.

Alternatively, the sample may permit the collection of both normal and atypical cells for analysis. The gene expression patterns for each of these two samples will be compared to each

- 21 -

other as well as the model and the normal versus individual abnormal comparisons therein based upon the reference data set. This approach can be significantly more powerful than the atypical cells only approach because it utilizes significantly more information from the normal cells and the differences between normal and atypical cells (in both the sample and reference data sets) to determine the status of the atypical cells from the sample.

By appropriate selection of the genes used in the analysis, identification of the relative amounts of atypical cells may also be possible, although in most clinical settings, the identification of the highest grade of breast cancer with confidence makes identification of lower grades less important. Stated differently, the identification of invasive cancer determines the clinical situation regardless of the presence of carcinoma *in situ* or hyperplastic cells, or the identification of carcinoma *in situ* makes determines the clinical situation regardless of the presence of hyperplastic cells.

With use of the present invention, skilled physicians may prescribe treatments based on non-invasive samples that they would have prescribed for a patient which had previously received a diagnosis via a solid tissue biopsy.

The above discussion is also applicable where a palpable lesion is detected followed by fine needle aspiration or needle biopsy of cells from the breast. The cells are plated and reviewed by a pathologist or automated imaging system which selects cells for analysis as described above. This again provides a means of linking visual to molecular cytology and provides a less subjective means of identifying the physiological state of breast cancer cells without the need for invasive solid tissue biopsies.

The present invention may also be used, however, with solid tissue biopsies. For example, a solid biopsy may be collected and prepared for visualization followed by determination of expression of one or more genes identified herein to determine the stage of breast cancer, if any. One preferred means is by use of *in situ* hybridization with polynucleotide or protein identifying probe(s) for assaying expression of said gene(s).

- 22 -

In an alternative method, the solid tissue biopsy may be used to extract molecules followed by analysis for expression of one or more gene(s). This provides the possibility of leaving out the need for visualization and collection of only those cells suspected of being atypical. This method may of course be modified such that only cells suspected of being atypical are collected and used to extract molecules for analysis. This would require visualization and selection as a prerequisite to gene expression analysis.

In a further modification of the above, both normal cells and cells suspected of being atypical are collected and used to extract molecules for analysis of gene expression. The approach, benefits and results are as described above using non-invasive sampling.

In a further alternative to all of the above, the gene(s) identified herein may be used as part of a simple PCR or array based assay simply to determine the presence of atypical cells in a sample from a non-invasive sampling procedure. This is simple to perform and utilizes genes identified to be the best discriminators of normal versus abnormal cells without the need for any cytological examination. If no atypical cells are identified, no cytological examination is necessary. If atypical cells are identified, cytological examination follows, and a more comprehensive analysis, as described above, may follow.

The genes identified herein may be used to generate a model capable of predicting the breast cancer stage (if any) of an unknown breast cell sample based on the expression of the identified genes in the sample. Such a model may be generated by any of the algorithms described herein or otherwise known in the art as well as those recognized as equivalent in the art using gene(s) (and subsets thereof) disclosed herein for the identification of whether an unknown or suspicious breast cancer sample is normal or is in one or more stages of breast cancer. The model provides a means for comparing expression profiles of gene(s) of the subset from the sample against the profiles of reference data used to build the model. The model can compare the sample profile against each of the reference profiles or against model defining delineations made based upon the reference profiles. Additionally, relative values from the sample profile may be used in comparison with the model or reference profiles.

- 23 -

In a preferred embodiment of the invention, breast cell samples identified as normal and abnormal (atypical) from the same subject may be analyzed for their expression profiles of the genes used to generate the model. This provides an advantageous means of identifying the stage of the abnormal sample based on relative differences from the expression profile of the normal sample. These differences can then be used in comparison to differences between normal and individual abnormal reference data which was also used to generate the model.

The detection of gene expression from the samples may be by use of a single microarray able to assay gene expression from all pairwise comparisons disclosed herein for convenience and accuracy.

Other uses of the present invention include providing the ability to identify breast cancer cell samples as being those of a particular stage of cancer for further research or study. This provides a particular advantage in many contexts requiring the identification of breast cancer stage based on objective genetic or molecular criteria rather than cytological observation. It is of particular utility to distinguish different grades of a particular breast cancer stage for further study, research or characterization because no objective criteria for such delineation was previously available.

The materials for use in the methods of the present invention are ideally suited for preparation of kits produced in accordance with well known procedures. The invention thus provides kits comprising agents for the detection of expression of the disclosed genes for identifying breast cancer stage. Such kits optionally comprising the agent with an identifying description or label or instructions relating to their use in the methods of the present invention, is provided. Such a kit may comprise containers, each with one or more of the various reagents (typically in concentrated form) utilized in the methods, including, for example, pre-fabricated microarrays, buffers, the appropriate nucleotide triphosphates (e.g., dATP, dCTP, dGTP and dTTP; or rATP, rCTP, rGTP and UTP), reverse transcriptase, DNA polymerase, RNA polymerase, and one or more primer complexes of the present invention (e.g., appropriate length

- 24 -

poly(T) or random primers linked to a promoter reactive with the RNA polymerase). A set of instructions will also typically be included.

The methods provided by the present invention may also be automated in whole or in part. All aspects of the present invention may also be practiced such that they consist essentially of a subset of the disclosed genes to the exclusion of material irrelevant to the identification of breast cancer stages in a cell containing sample.

Having now generally described the invention, the same will be more readily understood through reference to the following examples which are provided by way of illustration, and are not intended to be limiting of the present invention, unless specified.

EXAMPLES

Example I: Materials and Methods

Clinical specimens

Clinical biopsies from 30 patients were obtained from the Massachusetts General Hospital with Institutional Review Board approval. The tissue from one of the patients was not associated with breast cancer of any kind since it was from a breast reduction procedure. Pathological and histological information for the biopsies were also obtained. Three independent captures of about 1000 breast epithelial cells of one or more of the four different disease stages (normal, N; atypical ductal hyperplasia, ADH; ductal carcinoma *in situ*, DCIS; invasive ductal carcinoma, IDC) were procured from each biopsy using Laser Capture Microdissection (LCM, Arcturus Engineering). Three independent captures of LCIS (lobular carcinoma in situ) in one biopsy were also made. Total RNA was extracted from the captured (procured) cells and amplified with a T7-promoter based RNA amplification protocol. The human universal

- 25 -

reference RNA (Stratagene, La Jolla), was similarly amplified and used as the reference channel in a two-color microarray hybridization.

Microarrays

To maximize coverage of breast cancer-related genes on the microarrays used, 11,435 cDNA clones from the IMAGE consortium (Research Genetics) were obtained. These clones were selected based on literature knowledge (such as, but not limited to, preferential expression in cancer versus normal cells) and after mining (such as, but not limited to, preferential expression in breast tissues) gene expression information in the expressed sequence tags (EST) databases and the Serial Analysis of Gene Expression (SAGE) data sets available from the National Center for Biotechnology Information (NCBI, <http://www.ncbi.nlm.nih.gov>).

Microarray data processing

Microarray images were analyzed with ImaGene (BioDiscovery) to find and quantitate each spot on the microarray. Spots flagged by ImaGene as poor spots using standard criteria used with the software for the standardization of signals were excluded from further analysis. Raw Cy5 (sample channel) and Cy3 (reference channel) intensities and associated local background estimates for each spot were then examined. The signal/noise ratio, defined as the spot intensity over background intensity, was used as the second criteria for spot exclusion; spots with signal/noise ratio < 3.0 in the reference channel or < 1.5 in the sample channel were excluded from further analysis. Background-subtracted intensities across the chip were normalized to the 75th-percentile of the spot intensity distribution on the entire chip (alternative normalizations to the mean, median or other point may also be used as known in the art). Cy5/Cy3 ratios of each spot for each cellular state were averaged across each of six measurements (3 LCM captures x 2 chips/capture = 6 chips); outliers among the 6 data points were removed before taking the average. The resulting data were formatted as a data matrix

- 26 -

(samples along the top horizontal axis and gene identity along the vertical axis) for data mining (see Figure 1 with data).

Microarray data analysis

Before further analysis, each value in a row (gene) of the gene expression matrix was divided by the median value for the row, and the resulting matrix log-transformed. Normalized, median-centered, and log-transformed, gene expression data matrix was loaded into GeneMaths software (Applied-Maths, Belgium). Clustering and discriminant analysis were performed to identify sets of genes associated with different cellular states. For each pair-wise comparison between two breast cancer stages, samples are assigned to either the positive group or negative group, and genes were sorted by their discriminatory weights. The absolute value of the weight of a gene indicates the extent of difference in expression between the two groups; the positively signed genes are expressed higher in one group and the negatively signed genes are expressed higher in the other group.

The utility of the top-ranking genes as a diagnostic test was evaluated using the support vector machines (SVMs) algorithm (see Yeang, C. H., S. Ramaswamy, et al. (2001). "Molecular classification of multiple tumor types." *Bioinformatics* 17 Suppl 1: S316-22; Xiong, M., X. Fang, et al. (2001). "Biomarker identification by feature wrappers." *Genome Res* 11(11): 1878-87 **this one used linear discriminate analysis, logistic regression and svm**; Furey, T. S., N. Cristianini, et al. (2000). "Support vector machine classification and validation of cancer tissue samples using microarray expression data." *Bioinformatics* 16(10): 906-14; and Brown, M. P., W. N. Grundy, et al. (2000). "Knowledge-based analysis of microarray gene expression data by using support vector machines." *Proc Natl Acad Sci U S A* 97(1): 262-7, who state "SVMs are considered a supervised computer learning method because they exploit prior knowledge of gene function to identify unknown genes of similar function from expression data. SVMs avoid several problems associated with unsupervised clustering methods, such as hierarchical

- 27 -

clustering and self-organizing maps.”) Other algorithms, such as, but not limited to, linear discriminate analysis, logistic regression, cluster analysis, K-th nearest neighbor, or neural nets.

The support vector machines algorithm finds the maximal margin hyperplane that separate the two groups under comparison. The method of leave-one-out cross-validation was used to test the performance of a given set of genes; one sample was taken in turn out of the training set and a model is built using the rest of the training set, which is in then applied to classify the left-out sample. The accuracy of the genes in the cross-validation procedure is the percentage of correct classifications over the total number of the training samples.

Example II: 10 Genes for discriminating between ADH and DCIS

Based upon the methodology of Example I above, 10 genes identified as capable of discriminating between ADH and DCIS are listed in Table 1 below along with a brief description of the gene. CloneID as used in the context of the present invention refers to the IMAGE Consortium clone ID number of each gene, the sequences of which are hereby incorporated by reference in their entireties as they are available from the Consortium at <http://image.llnl.gov/> as accessed on the filing date of the present application. Weight refers to the absolute value indicating the extent of difference in expression between ADH and DCIS where the positively signed values are expressed higher in ADH and the negatively signed values are expressed higher in DCIS; Chromosome Location refers to the human chromosome to which the gene has been assigned, and Description provides a brief identifier of what the gene encodes. The actual data corresponding to the assigned weights are shown in Figure 2.

Table 1

GeneID	Weight	Chromosome Location	Description
825470	0.9946555	17q21-q22	topoisomerase (DNA) II alpha (170kD)

Example III: Genes for discriminating between normal and non-normal (a combination of ADH, DCIS, and IDC) cells from breast tissue

As shown in Table 2 below, 850 genes were identified as being able to discriminate between normal and "abnormal" (defined in this instance as any sample that was not normal), which includes ADH, DCIS and IDC.

Example IV: Genes for discriminating between normal and ADH

As shown in Table 3 below, 600 genes were identified as being able to discriminate between normal and ADH.

Table 3

CloneID	Weight	Description
1323448	1.3237504	cysteine-rich protein 1 (intestinal)
594500	1.158305	EST
824052	1.034408	chromosome 6 open reading frame 1

Example V: Genes for discriminating between normal and DCIS

As shown in Table 4 below, 1300 genes were identified as being able to discriminate between normal and DCIS.

Table 4

CloneID	Weight	Description
1323448	1.397391	cysteine-rich protein 1 (intestinal)
788654	1.2615322	growth factor receptor-bound protein 2
1505038	1.1904802	hypothetical protein FLJ20171
745606	1.1825585	hypothetical protein PP591

- 80 -

565319	1.0969429	Homo sapiens mRNA; cDNA DKFZp564B1264 (from clone DKFZp564B1264)
35147	1.0886084	ESTs, Weakly similar to unnamed protein product [H.sapiens]
178805	1.0274897	Human DNA sequence from clone RP5-850E9 on chromosome 20. Contains part of the gene for a novel C2H2 type zinc finger protein similar to Drosophila Scratch (Scrt), Slug and Xenopus Snail, a novel gene similar to Drosophila CG6762, STSs, GSSs and five CpG
796469	1.0269115	HSPC150 protein similar to ubiquitin-conjugating enzyme
1609836	1.0164283	glutamate-ammonia ligase (glutamine synthase)
366132	1.013995	succinate dehydrogenase complex, subunit C, integral membrane protein, 15kD
1500000	1.0118809	H2B histone family, member B
812238	1.0043787	hypothetical protein MGC4692
595037	0.990461	retinoic acid induced 3
1554549	0.9764206	hydroxyacyl glutathione hydrolase
488964	0.9569176	H2A histone family, member O
138189	0.9386802	Wolfram syndrome 1 (wolframin)
283919	0.937383	H2A histone family, member L
823598	0.9153521	proteasome (prosome, macropain) 26S subunit, non-ATPase, 12
810711	0.9128832	stearoyl-CoA desaturase (delta-9-desaturase)
1911343	0.9116745	RAB26, member RAS oncogene family
503215	0.9108688	pilin-like transcription factor
811774	0.9073627	CGI-49 protein
122077	0.9021901	putative membrane protein
1492238	0.9019233	HSPC003 protein
469686	0.8919992	Ric (Drosophila)-like, expressed in many tissues
685516	0.8762873	putative G protein-coupled receptor
359887	0.8692353	translocase of inner mitochondrial membrane 17 (yeast) homolog A
131094	0.8675719	Homo sapiens cDNA: FLJ21587 fis, clone COL06946
1492463	0.8634521	selenoprotein X, 1

- 81 -

843195	0.8603524	phosphoserine phosphatase
796723	0.8573155	Homo sapiens clone CDABP0014 mRNA sequence
488202	0.8463961	ESTs, Weakly similar to YZ28_HUMAN HYPOTHETICAL PROTEIN ZAP128 [H.sapiens]
1492426	0.8445255	chromosome 19 open reading frame 3
280375	0.8392836	PRO2000 protein
290841	0.8346933	H2B histone family, member A
1917941	0.8340565	purine-rich element binding protein B
1469425	0.8296141	SRY (sex determining region Y)-box 22
2016908	0.8282806	ESTs, Weakly similar to CA13_HUMAN COLLAGEN ALPHA 1(III) CHAIN PRECURSOR [H.sapiens]
471568	0.8264546	hematological and neurological expressed 1
150003	0.8251408	hypothetical protein FLJ13187
2029173	0.8213721	ESTs, Weakly similar to N-WASP [H.sapiens]
731044	0.8169506	glutaredoxin 2
244801	0.8066357	Rho guanine exchange factor (GEF) 11
2054635	0.7914755	proteasome (prosome, macropain) subunit, alpha type, 7
1605426	0.787298	hypothetical protein FLJ13352
1709791	0.7837549	BAI1-associated protein 1
470061	0.77977	seven in absentia (Drosophila) homolog 2
1640821	0.7790286	ESTs, Weakly similar to I78885 serine/threonine-specific protein kinase [H.sapiens]
199403	0.7754748	lectin, galactoside-binding, soluble, 8 (galectin 8)
741474	0.7732047	glucose phosphate isomerase
1435862	0.7697423	antigen identified by monoclonal antibodies 12E7, F21 and O13
239568	0.767277	annexin A9
841679	0.7666686	calcium and integrin binding protein (DNA-dependent protein kinase interacting protein)
729975	0.7649717	meningioma expressed antigen 5 (hyaluronidase)
2016648	0.7633048	Homo sapiens mRNA; cDNA DKFZp434N1728 (from clone DKFZp434N1728)
2052113	0.7627076	hypothetical protein FLJ10903

Example VI: Genes for discriminating between normal and ADH (non-malignant) versus DCIS and IDC (malignant)

As shown in Table 5 below, 400 genes were identified as being able to discriminate between normal and ADH (non-malignant) versus DCIS and IDC (malignant).

Table 5

ClonID	Weight	Description
796469	1.4207633	HSPC150 protein similar to ubiquitin-conjugating enzyme
488964	1.3447179	H2A histone family, member O

Example VII: Genes for discriminating between ADH and DCIS

As shown in Table 6 below, 350 genes were identified as being able to discriminate between ADH and DCIS. The actual data is shown in Figure 3.

Table 6

ClonID	Weight	Description
1404774	-0.5685596	parathyroid hormone-like hormone

Example VIII: Genes for discriminating between DCIS Grade I and Grade III

As shown in Table 7 below, 350 genes were identified as being able to discriminate between grades of DCIS. The actual data corresponding to this table is shown in Figure 4.

Table 7

CloneID	Weight	Description
2460159	4.6268975	tyrosine kinase, non-receptor, 1
358151	2.8783989	zinc finger protein 33a (KOX 31)

795382	2.772572	Rap1 guanine-nucleotide-exchange factor directly activated by cAMP
714472	2.6829714	KIAA0397 gene product
725649	2.6433625	nuclear factor of activated T-cells, cytoplasmic, calcineurin-dependent 4
51218	2.6200167	ESTs
504959	2.5777963	Homo sapiens mRNA; cDNA DKFZp586G0321 (from clone DKFZp586G0321)
647397	2.5320153	ESTs
814815	2.4198892	plakophilin 4
279720	2.4136316	ESTs, Moderately similar to A47582 B-cell growth factor precursor [H.sapiens]
298231	2.4096172	gamma-aminobutyric acid (GABA) B receptor, 1
172783	2.3339699	hypothetical protein FLJ10390
261609	2.311051	ESTs, Weakly similar to S65657 alpha-1C-adrenergic receptor splice form 2 [H.sapiens]
826668	2.2951137	KIAA0274 gene product
1493383	2.2616737	Homo sapiens mRNA; cDNA DKFZp434H2418 (from clone DKFZp434H2418)
2017756	2.2403622	homolog of yeast MOG1
1455566	2.1756946	adenosine A3 receptor
725321	2.1658095	estrogen receptor 1
180561	2.1393944	glutathione S-transferase M4
32050	2.1165022	Homo sapiens mRNA; cDNA DKFZp586P1124 (from clone DKFZp586P1124)
215000	2.1150123	vasoactive intestinal peptide receptor 1
2019750	2.0957741	SEC14 (S. cerevisiae)-like 2
283124	2.0921779	ESTs, Moderately similar to LONG-CHAIN FATTY ACID TRANSPORT PROTEIN [M.musculus]
490615	2.0635424	tubulin, gamma 2
666138	2.0625667	hypothetical protein DKFZp761J1523
418129	2.0541212	nuclear mitotic apparatus protein 1
1733262	2.052666	BLu protein
1588791	2.044069	O-6-methylguanine-DNA methyltransferase
461761	2.035953	angiogenin, ribonuclease, RNase A family, 5

712139 -1.4735772 ADP-ribosylation factor-like 7

- 162 -

785368 -1.4680554 PDZ-binding kinase; T-cell originated protein kinase
825606 -1.4667088 kinesin-like 1
531319 -1.4659871 serine/threonine kinase 12
66406 -1.4641179 hypothetical protein DKFZp762E1312
470124 -1.4635711 RAD1 (S. pombe) homolog

Example IX: Genes for discriminating between IDC Grade I and Grade III

As shown in Table 8 below, 300 genes were identified as being able to discriminate between two grades of IDC.

Table 8

ClonID	Weight	Description
1706635	3.279305	bone gamma-carboxyglutamate (gla) protein (osteocalcin)
666138	3.1366533	hypothetical protein DKFZp761J1523
795382	3.0005724	Rap1 guanine-nucleotide-exchange factor directly activated by cAMP
364865	2.8512705	hypothetical protein FLJ21062
1500542	2.8021264	regulator of G-protein signalling 11
270127	2.7455118	
588262	2.7127609	Homo sapiens, Similar to RIKEN cDNA 2600001A11 gene, clone MGC:9907 IMAGE:3870073, mRNA, complete cds
277266	2.5004627	Homo sapiens, clone IMAGE:3625550, mRNA, partial cds
2090129	2.4882736	chromobox homolog 2 (Drosophila Pc class)
325583	2.4558352	EST
358151	2.4309122	zinc finger protein 33a (KOX 31)
786675	2.3877233	epididymis-specific, whey-acidic protein type, four-disulfide core; putative ovarian carcinoma marker
854763	2.378956	Homo sapiens cDNA FLJ11341 fis, clone PLACE1010786
1592976	2.3417116	microphthalmia-associated transcription factor

- 163 -

1562231 2.286418 SET binding protein 1
767176 2.2472282 tumor necrosis factor (ligand) superfamily, member 13

263790 -1.9904129 isocitrate dehydrogenase 3 (NAD+) alpha
549349 -1.9893582 hypothetical protein PRO1068
109221 -1.9879196 KIAA0286 protein
51773 -1.9875155 hypothetical protein MGC3077

Example X: Crossvalidation

- 173 -

The following table shows the results of crossvalidation analysis (as described in Example I above) of various pair-wise comparisons. The two members of the pairwise comparison are indicated as "Class 1" and "Class 2" with the number of samples analyzed indicated under "N". The number of genes used to predict is indicated, along with the accuracy (in percent) for each combination. "FP" and "FN" refer to "false positive" and "false negative", respectively, as incorrectly identified for each of the two classes.

Class 1 Name	N	Class 2 Name	N	Genes	Accuracy	Class 1 FP	Class 1 FN	Class 2 FP	Class 2 FN
Normal	28	Abnormal	57	850	99	0	1	1	0
Normal	28	ADH	7	600	100	0	0	0	0
Normal	28	DCIS	28	1300	100	0	0	0	0
ADH	7	DCIS	28	350	97	0	1	1	0
ADH	7	DCIS	28	10	97	0	1	1	0
N+ADH	36	DCIS+IDC	49	400	98	1	1	1	1
DCIS-I	7	DCIS-III	9	300	100	0	0	0	0
IDC-I	4	IDC-III	8	300	100	0	0	0	0

All references cited herein, including patents, patent applications, and publications, are hereby incorporated by reference in their entireties, whether previously specifically incorporated or not.

Having now fully described this invention, it will be appreciated by those skilled in the art that the same can be performed within a wide range of equivalent parameters, concentrations, and conditions without departing from the spirit and scope of the invention and without undue experimentation.

While this invention has been described in connection with specific embodiments thereof, it will be understood that it is capable of further modifications. This application is intended to cover any variations, uses, or adaptations of the invention following, in general, the principles of the invention and including such departures from the present disclosure as come within known or customary practice within the art to which the invention pertains and as may be applied to the essential features hereinbefore set forth.
